

Ensemble Classifiers

- IDEA:
 - do not learn a *single* classifier but learn a *set of classifiers*
 - *combine the predictions* of multiple classifiers
- MOTIVATION:
 - reduce variance: results are less dependent on peculiarities of a single training set
 - reduce bias: a combination of multiple classifiers may learn a more expressive concept class than a single classifier
- KEY STEP:
 - formation of an ensemble of *diverse* classifiers from a single training set

Forming an Ensemble

- Modifying the data
 - Subsampling
 - bagging
 - boosting
 - feature subsets
 - randomly feature samples
- Modifying the learning task
 - pairwise classification / round robin learning
 - error-correcting output codes
- Exploiting the algorithm characteristics
 - algorithms with random components
 - neural networks
 - randomizing algorithms
 - randomized decision trees
 - use multiple algorithms with different characteristics
- Exploiting problem characteristics
 - e.g., hyperlink ensembles

Bagging

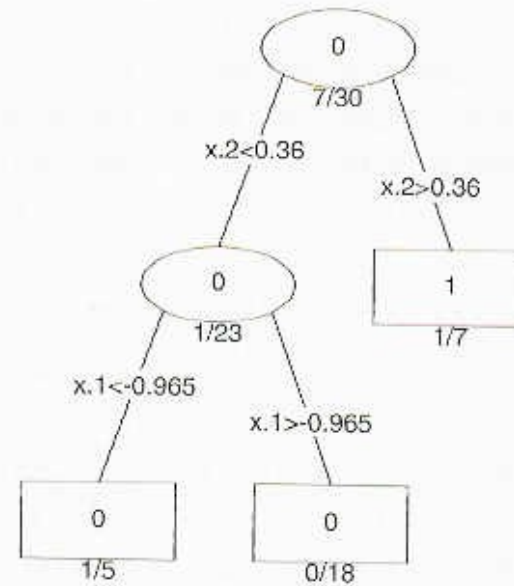

1. for $m = 1$ to M // M ... number of iterations
 - a) draw (with replacement) a bootstrap sample S_m of the data
 - b) learn a classifier C_m from S_m
2. for each test example
 - a) try all classifiers C_m
 - b) predict the class that receives the highest number of votes

- variations are possible
 - e.g., size of subset, sampling w/o replacement, etc.
- many related variants
 - sampling of features, not instances
 - learn a set of classifiers with different algorithms

Bagged Trees

weighted voting
voting

Boosting

- Basic Idea:
 - later classifiers focus on examples that were misclassified by earlier classifiers
 - weight the predictions of the classifiers with their error
- Realization
 - perform multiple iterations
 - each time using different example weights
 - weight update between iterations
 - increase the weight of incorrectly classified examples
 - this ensures that they will become more important in the next iterations
(misclassification errors for these examples count more heavily)
 - combine results of all iterations
 - weighted by their respective error measures

Dealing with Weighted Examples

Two possibilities (→ cost-sensitive learning)

- directly
 - example e_i has weight w_i
 - number of examples $n \Rightarrow$ total example weight $\sum_{i=1}^n w_i$
- via sampling
 - interpret the weights as probabilities
 - examples with larger weights are more likely to be sampled
 - assumptions
 - sampling with replacement
 - weights are well distributed in $[0, 1]$
 - learning algorithm sensible to varying numbers of identical examples in training data

Boosting – Algorithm AdaBoost

1. initialize example weights $w_i = 1/N$ ($i = 1..N$)
2. for $m = 1$ to M // M ... number of iterations
 - a) learn a classifier C_m using the current example weights
 - b) compute a **weighted error estimate**
$$err_m = \frac{\sum w_i \text{ of all incorrectly classified } e_i}{\sum_{i=1}^N w_i}$$
 - c) compute a **classifier weight** $\alpha_m = \frac{1}{2} \log\left(\frac{1 - err_m}{err_m}\right)$
 - d) for all **correctly** classified examples e_i : $w_i \leftarrow w_i e^{-\alpha_m}$
 - e) for all **incorrectly** classified examples e_i : $w_i \leftarrow w_i e^{\alpha_m}$
 - f) normalize the weights w_i so that they sum to 1
3. for each test example
 - a) try all classifiers C_m
 - b) predict the class that receives the highest sum of weights α_m

Illustration of the Weights

- Classifier Weights α_m
 - differences near 0 or 1 are emphasized

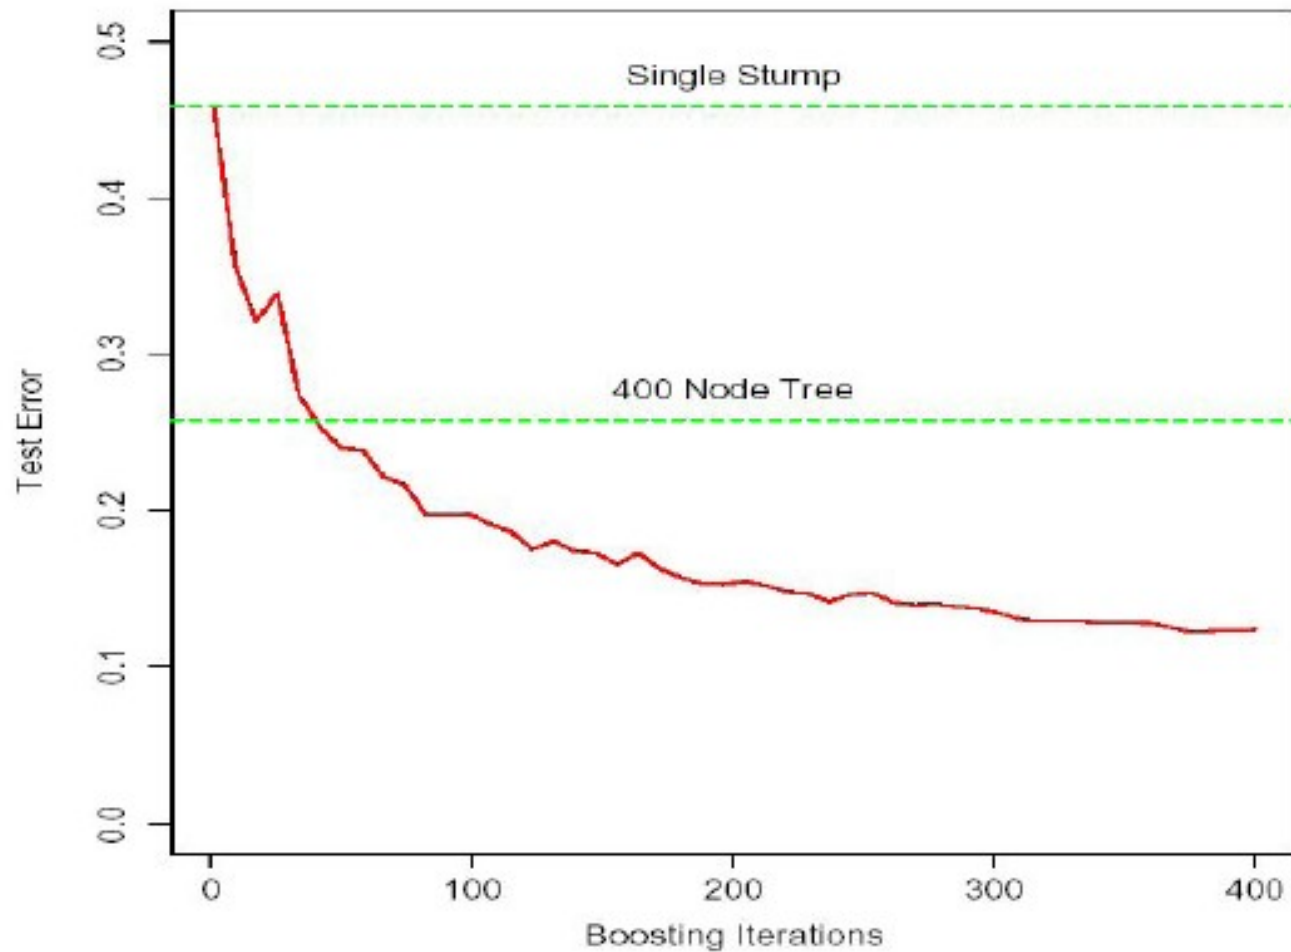

- Example Weights
 - multiplier for correct and incorrect examples, depending on error

Boosting – Error rate example

- boosting of decision stumps on simulated data

Toy Example

(taken from Verma & Thrun, Slides to CALD Course CMU 15-781, Machine Learning, Fall 2000)

Round 1

Round 2

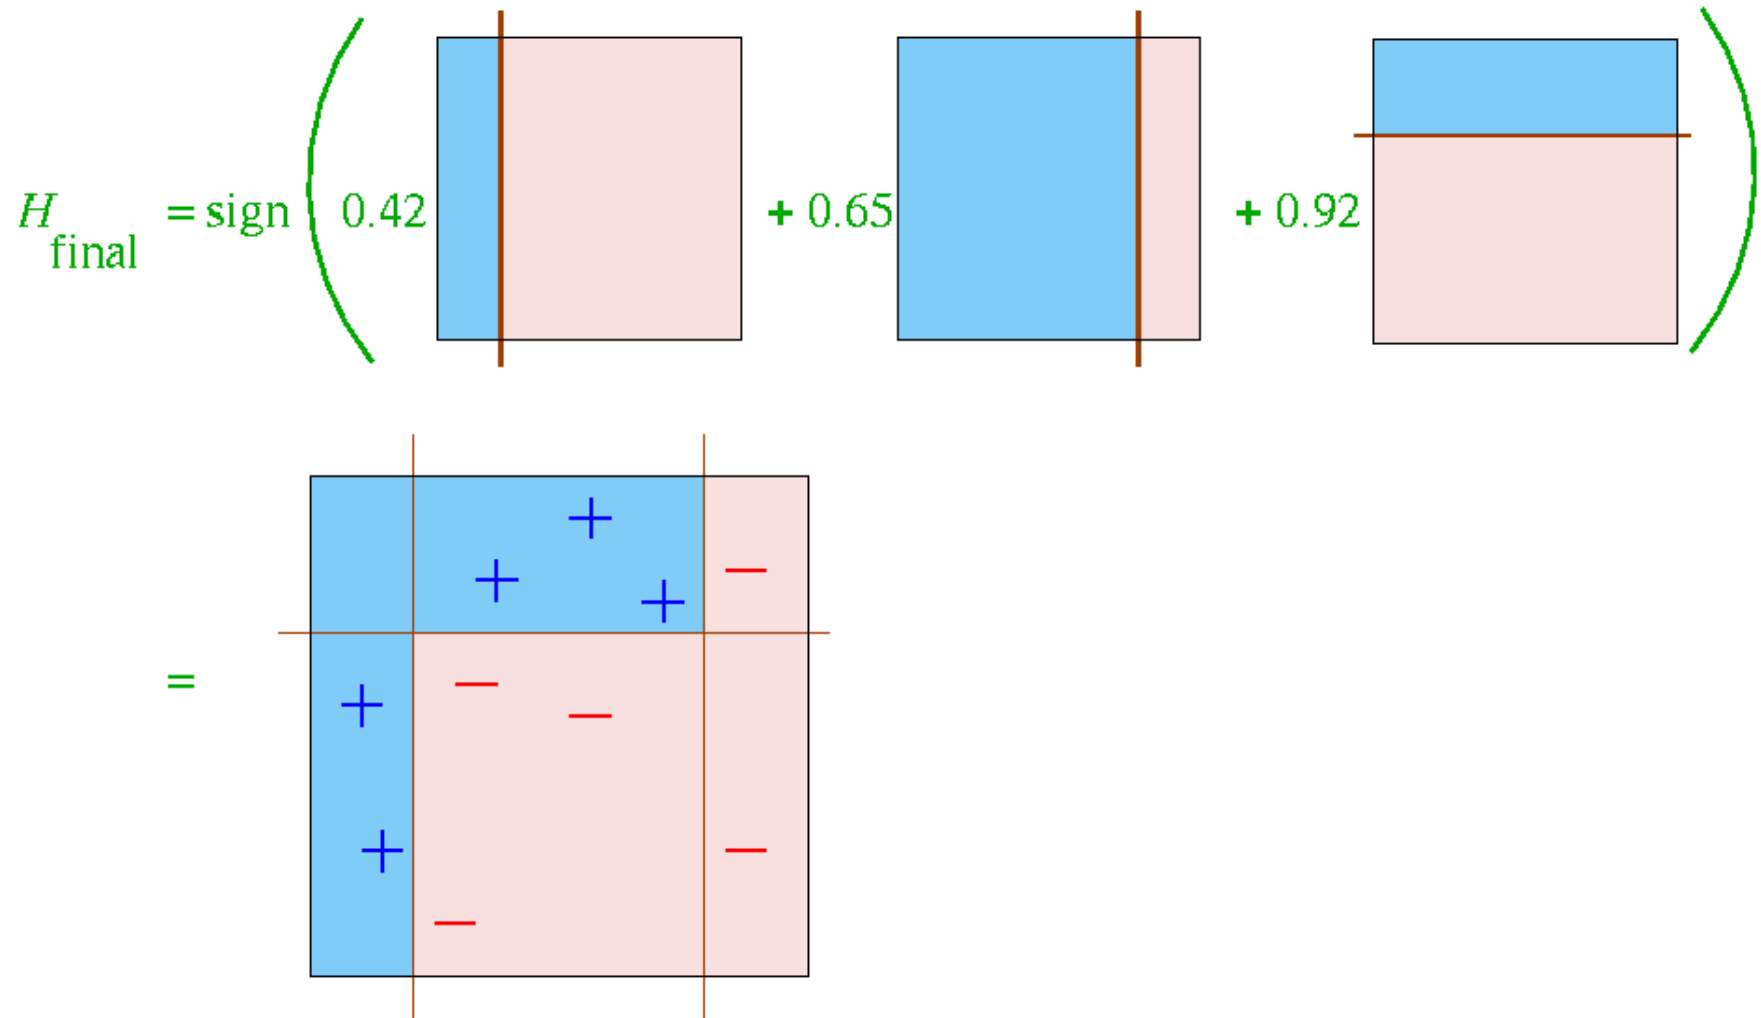

Round 3

$$\epsilon_3 = 0.14$$

$$\alpha_3 = 0.92$$

Final Hypothesis

Example

FIGURE 8.11. Data with two features and two classes, separated by a linear boundary. Left panel: decision boundary estimated from bagging the decision rule from a single split, axis-oriented classifier. Right panel: decision boundary from boosting the decision rule of the same classifier. The test error rates are 0.166, and 0.065 respectively. Boosting is described in Chapter 10.

Comparison Bagging/Boosting

- Bagging
 - noise-tolerant
 - produces better class probability estimates
 - not so accurate
 - statistical basis
 - related to random sampling
- Boosting
 - very susceptible to noise in the data
 - produces rather bad class probability estimates
 - if it works, it works really well
 - based on learning theory (statistical interpretations are possible)
 - related to windowing

Combining Predictions

- voting
 - each ensemble member votes for one of the classes
 - predict the class with the highest number of vote (e.g., bagging)
- weighted voting
 - make a *weighted* sum of the votes of the ensemble members
 - weights typically depend
 - on the classifiers confidence in its prediction (e.g., the estimated probability of the predicted class)
 - on error estimates of the classifier (e.g., boosting)
- stacking
 - Why not use a classifier for making the final decision?
 - training material are the class labels of the training data and the (cross-validated) predictions of the ensemble members

Stacking

- Basic Idea:
 - learn a function that combines the predictions of the individual classifiers
- Algorithm:
 - train n different classifiers $C_1 \dots C_n$ (the *base classifiers*)
 - obtain predictions of the classifiers for the training examples
 - better do this with a cross-validation!
 - form a new data set (the *meta data*)
 - **classes**
 - the same as the original dataset
 - **attributes**
 - one attribute for each base classifier
 - value is the prediction of this classifier on the example
 - train a separate classifier M (the *meta classifier*)

Stacking (2)

- Example:

Attributes			Class
x_{11}	...	x_{1n_a}	t
x_{21}	...	x_{2n_a}	f
...
x_{n_e1}	...	$x_{n_en_a}$	t

training set

C_1	C_2	...	C_{n_c}
t	t	...	f
f	t	...	t
...
f	f	...	t

predictions of the classifiers

C_1	C_2	...	C_{n_c}	Class
t	t	...	f	t
f	t	...	t	f
...
f	f	...	t	t

training set for stacking

- Using a stacked classifier:
 - try each of the classifiers $C_1 \dots C_n$
 - form a feature vector consisting of their predictions
 - submit this feature vectors to the meta classifier M
